COMP 3331/9331: Computer Networks and Applications

Week 8

Network Layer: Data Plane + Control Plane (Routing)

Chapter 4: Section 4.3

Chapter 5: Section 5.1 – 5.2, 5.6

Network Layer, data plane: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

IPv6: motivation

- initial motivation: 32-bit address space soon to be completely allocated.
- additional motivation:
 - header format helps speed processing/forwarding
 - header changes to facilitate QoS

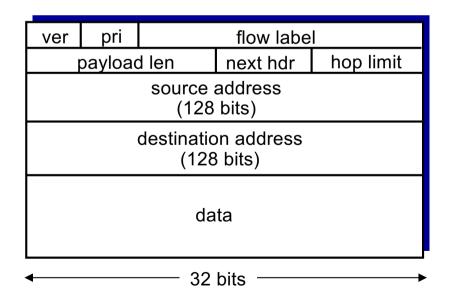

IPv6 datagram format:

- fixed-length 40 byte header
- no fragmentation allowed

IPv6 datagram format

priority: identify priority among datagrams in flow (traffic class) flow Label: identify datagrams in same "flow." (concept of flow not well defined).

next header: identify upper layer protocol for data

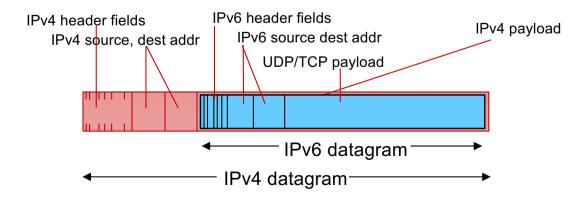

Other changes from IPv4

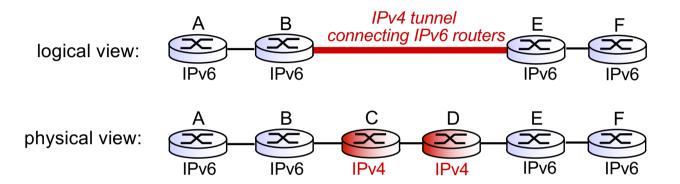

- checksum: removed entirely to reduce processing time at each hop
- options: allowed, but outside of header, indicated by "Next Header" field
- ❖ ICMPv6: new version of ICMP
 - additional message types, e.g. "Packet Too Big"
 - multicast group management functions

Transition from IPv4 to IPv6

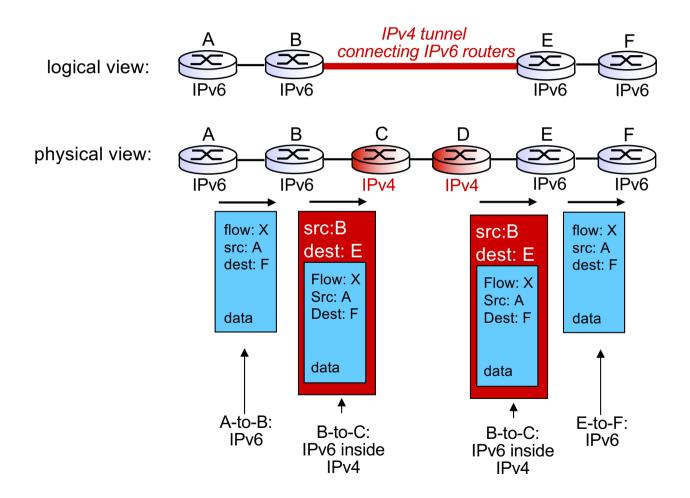

- not all routers can be upgraded simultaneously
 - no "flag days"
 - how will network operate with mixed IPv4 and IPv6 routers?
- tunneling: IPv6 datagram carried as payload in IPv4 datagram among IPv4 routers

Tunneling (IPv6 over IPv4)

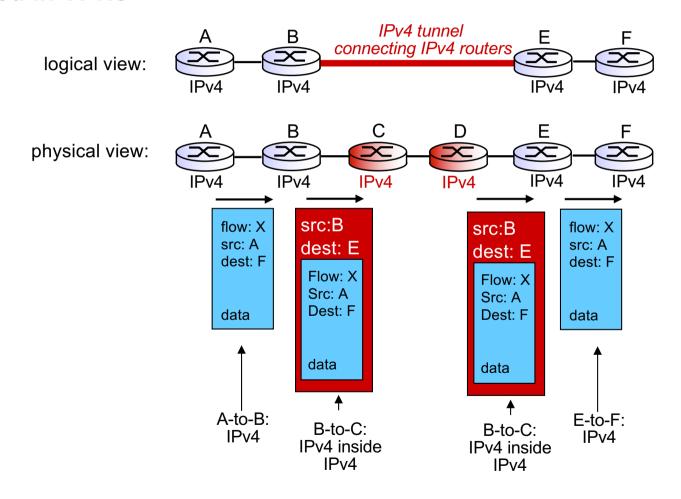

Tunneling (IPv6 over IPv4)

Tunneling (IPv4 over IPv4)

Used in VPNs

Network layer, control plane: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- hierarchical routing

5.6 ICMP: The Internet Control Message Protocol

Self study (not on exam)

Network-layer functions

Recall: two network-layer functions:

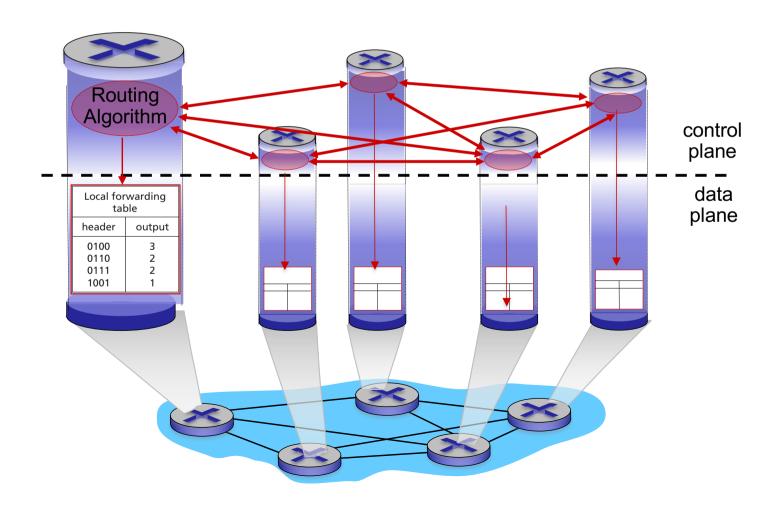

- forwarding: move packets
 from router's input to
 appropriate router output
- routing: determine route taken by packets from source Control plane to destination

Two approaches to structuring network control plane:

- per-router control (traditional)
- logically centralized control (software defined networking)

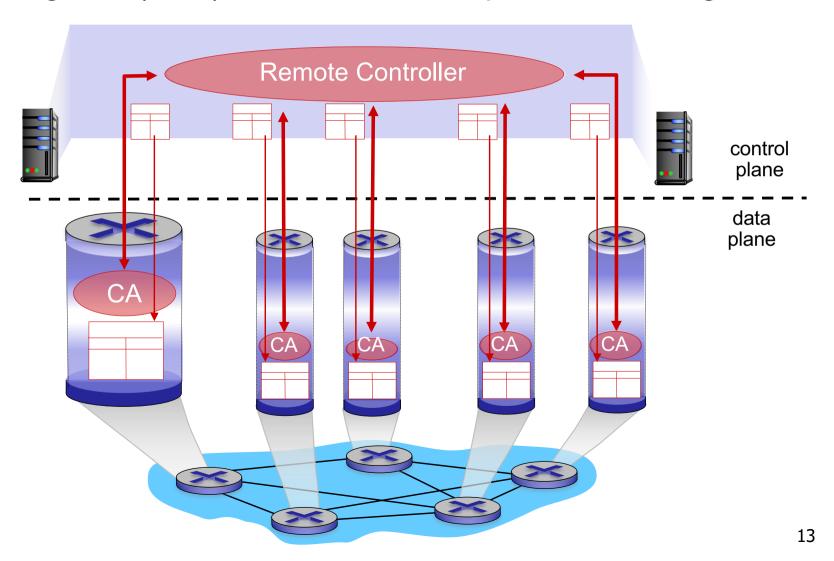

Per-router control plane

Individual routing algorithm components in each and every router interact with each other in control plane to compute forwarding tables

Logically centralized control plane

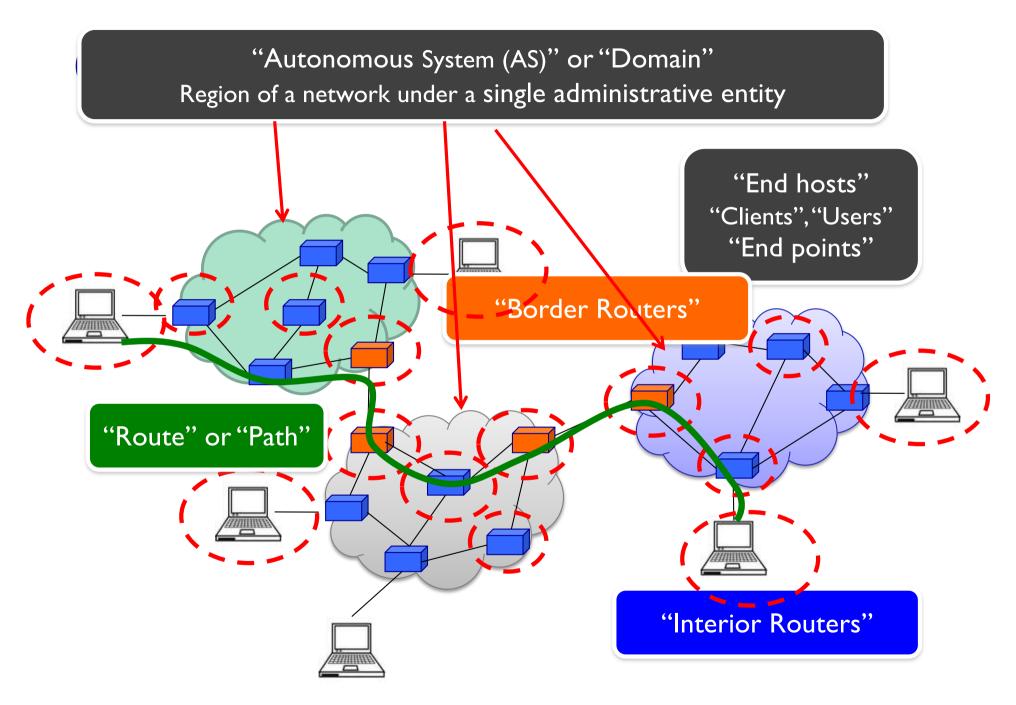

A distinct (typically remote) controller interacts with local control agents (CAs) in routers to compute forwarding tables

Network layer, control plane: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- Hierarchical routing

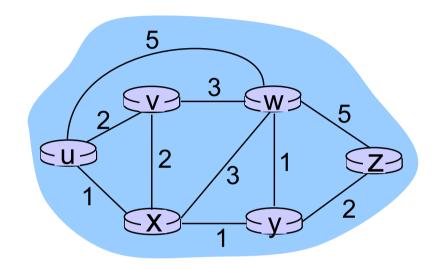

5.6 ICMP: The Internet Control Message Protocol

Internet Routing

- Internet Routing works at two levels
- Each AS runs an intra-domain routing protocol that establishes routes within its domain
 - AS -- region of network under a single administrative entity
 - Link State, e.g., Open Shortest Path First (OSPF)
 - Distance Vector, e.g., Routing Information Protocol (RIP)
- ASes participate in an inter-domain routing protocol that establishes routes between domains
 - Path Vector, e.g., Border Gateway Protocol (BGP)

Graph abstraction

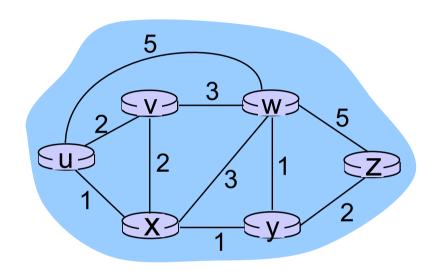

graph: G = (N,E)

 $N = set of routers = \{ u, v, w, x, y, z \}$

 $E = \text{set of links} = \{ (u,v), (u,x), (u,w), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

Graph abstraction: costs

$$c(x,x') = cost of link (x,x')$$

e.g., $c(w,z) = 5$

cost of path
$$(x_1, x_2, x_3, ..., x_p) = c(x_1, x_2) + c(x_2, x_3) + ... + c(x_{p-1}, x_p)$$

key question: what is the least-cost path between u and z? routing algorithm: algorithm that finds that least cost path

Link Cost

- Typically simple: all links are equal
- Least-cost paths => shortest paths (hop count)
- Network operators add policy exceptions
 - Lower operational costs
 - Peering agreements
 - Security concerns

Network layer, control plane: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- hierarchical routing

5.6 ICMP: The Internet Control Message Protocol

Routing algorithm classes

Link State (Global)

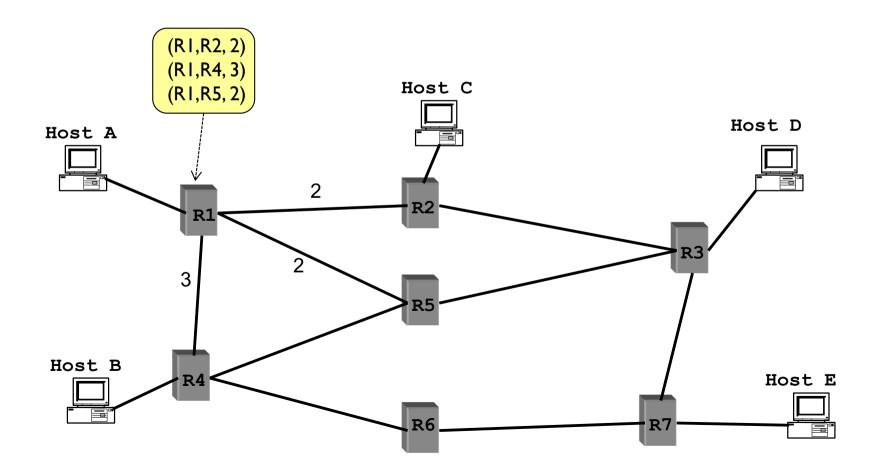

- Routers maintain cost of each link in the network
- Connectivity/cost changes flooded to all routers
- Converges quickly (less inconsistency, looping, etc.)
- Limited network sizes

Distance Vector (Decentralised)

- Routers maintain next hop & cost of each destination.
- Connectivity/cost changes iteratively propagate form neighbour to neighbour
- Requires multiple rounds to converge
- Scales to large networks

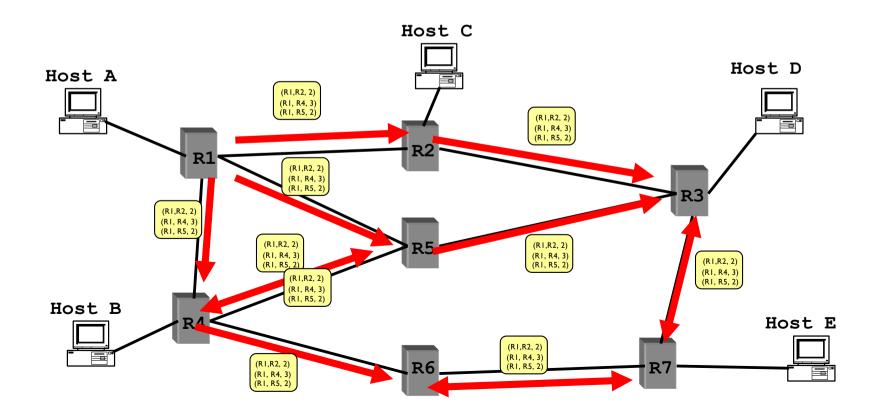

Link State Routing

- Each node maintains its local "link state" (LS)
 - i.e., a list of its directly attached links and their costs

Link State Routing

- Each node maintains its local "link state" (LS)
- Each node floods its local link state
 - on receiving a new LS message, a router forwards the message to all its neighbors other than the one it received the message from

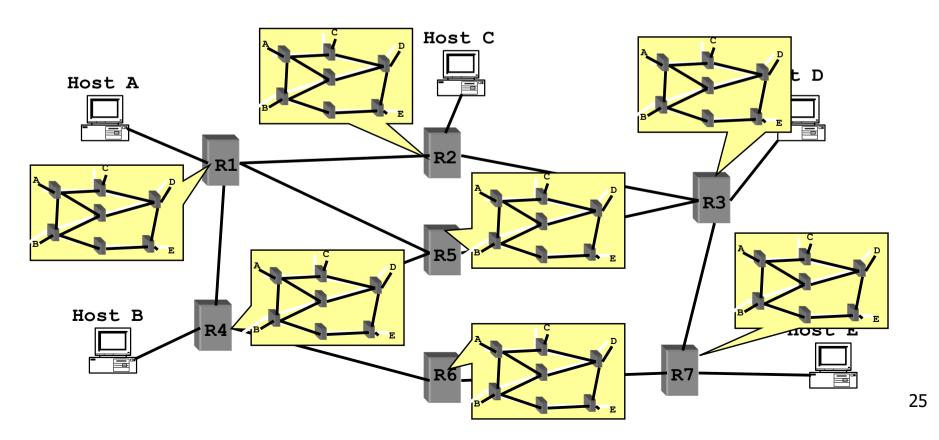

Flooding LSAs

- Routers transmit Link State Advertisement (LSA)
 on links
 - A neighbouring router forwards out on all links except incoming
 - Keep a copy locally; don't forward previously-seen LSAs
- Challenges
 - Packet loss
 - Out of order arrival
- Solutions
 - Acknowledgements and retransmissions
 - Sequence numbers
 - Time-to-live for each packet

Link State Routing

- Each node maintains its local "link state" (LS)
- Each node floods its local link state
- Eventually, each node learns the entire network topology
 - Can use Dijkstra's to compute the shortest paths between nodes

A Link-State Routing Algorithm

Dijkstra 's algorithm

- net topology, link costs known to all nodes
 - accomplished via "link state broadcast"
 - all nodes have same info
- computes least cost paths from one node ('source") to all other nodes
 - gives forwarding table for that node
- iterative: after k iterations, know least cost path to k dest.'s

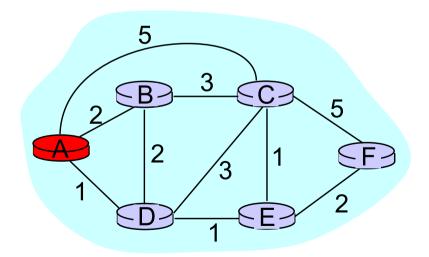

notation:

- * C(X,y): link cost from node x to y; = ∞ if not direct neighbors
- D(V): current value of cost of path from source to dest. v
- p(V): predecessor node along path from source to
- N': set of nodes whose least cost path definitively known

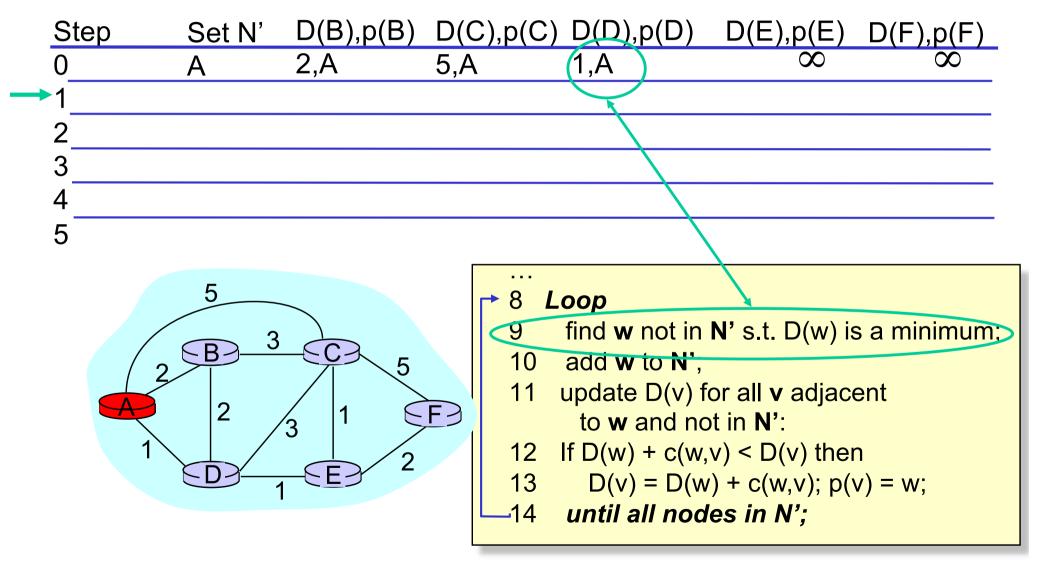

Dijsktra's Algorithm

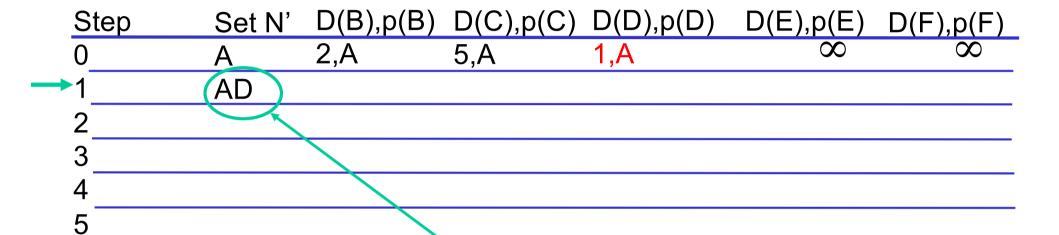

```
Initialization:
   N' = \{u\}
   for all nodes v
   if v adjacent to u
       then D(v) = c(u,v)
    else D(v) = \infty
  Loop
    find w not in N' such that D(w) is a minimum
   add w to N'
   update D(v) for all v adjacent to w and not in N':
      D(v) = \min(D(v), D(w) + c(w,v))
   /* new cost to v is either old cost to v or known
14
     shortest path cost to w plus cost from w to v */
15 until all nodes in N'
```

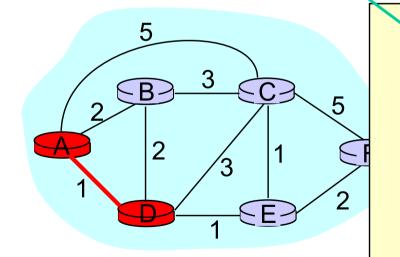

Step	Set N'	D(B),p(B)	D(C),p(C)	D(D),p(D)	D(E),p(E)	D(F),p(F)
0	Α	2,A	5,A	1,A	∞	∞
1						
2						
3						
4						
5						

```
    1 Initialization:
    2 N' = {A};
    3 for all nodes v
    4 if v adjacent to A
    5 then D(v) = c(A,v);
    6 else D(v) = ∞;
    ...
```

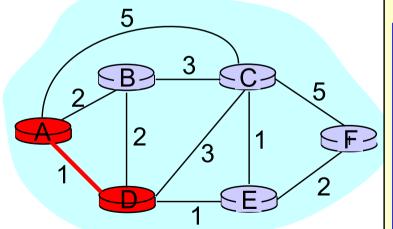

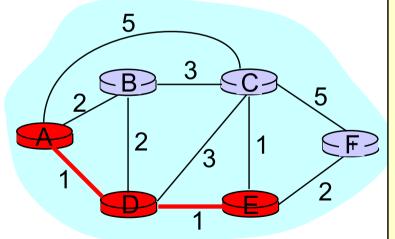

```
8 Loop
9 find w not in N' s.t. D(w) is a minimum;
10 add w to N';
11 update D(v) for all v adjacent to w and not in N':
12 If D(w) + c(w,v) < D(v) then</li>
13 D(v) = D(w) + c(w,v); p(v) = w;

5	ADEBCE					

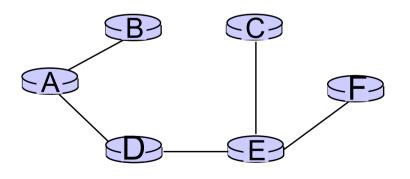

To determine path $A \rightarrow C$ (say), work backward from C via p(v)

The Forwarding Table

- Running Dijkstra at node A gives the shortest path from A to all destinations
- We then construct the forwarding table

resulting shortest-path tree from A:

Destination	Link
В	(A,B)
С	(A,D)
D	(A,D)
E	(A,D)
F	(A,D)

Issue #1: Scalability

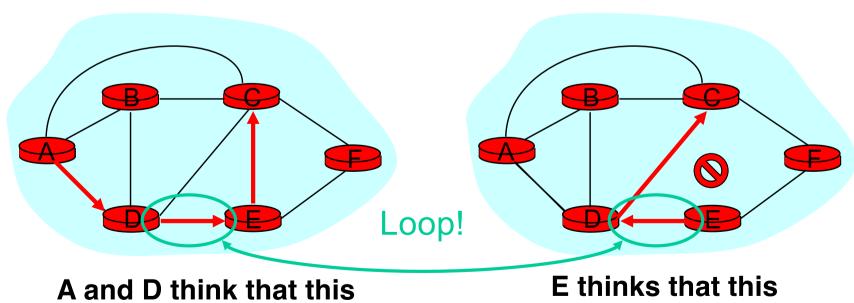

- How many messages needed to flood link state messages?
 - O(N x E), where N is #nodes; E is #edges in graph
- Processing complexity for Dijkstra's algorithm?
 - $O(N^2)$, because we check all nodes w not in N' at each iteration and we have O(N) iterations
- \bullet How many entries in the LS topology database? O(E)
- \star How many entries in the forwarding table? O(N)

Issue#2: Transient Disruptions

Inconsistent link-state database

is the path to C

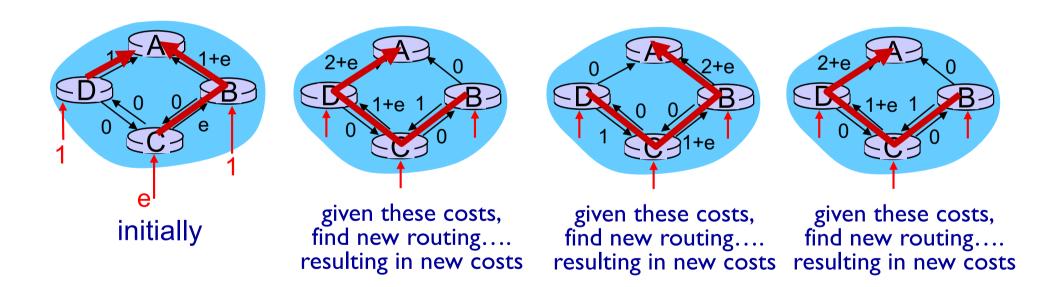

- Some routers know about failure before others
- The shortest paths are no longer consistent
- Can cause transient forwarding loops

Oscillations

oscillations possible:

• e.g., suppose link cost equals amount of carried traffic:

Network layer, control plane: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- hierarchical routing

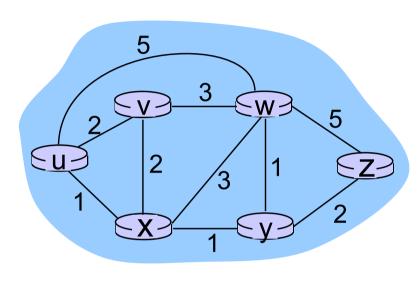

5.6 ICMP: The Internet Control Message Protocol

Distance vector algorithm

Bellman-Ford equation

```
let
  d_{x}(y) := cost of least-cost path from x to y
then
  d_{x}(y) = \min_{x} \{c(x,v) + d_{v}(y)\}
                             cost from neighbor v to destination y
                    cost to neighbor v
             min taken over all neighbors v of x
```

Bellman-Ford example

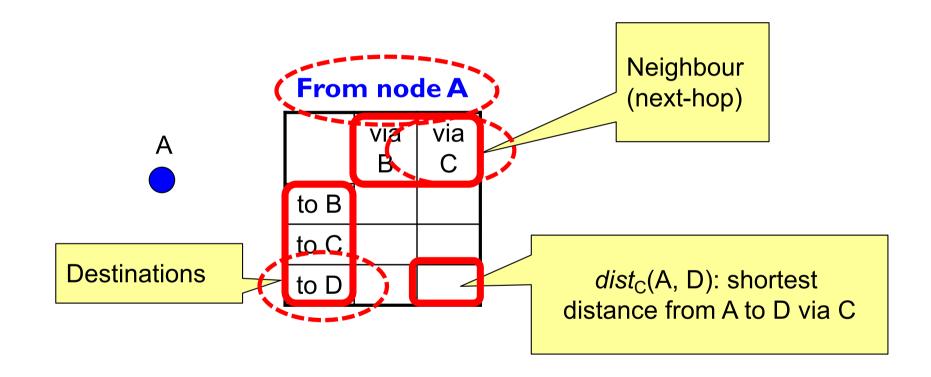

clearly,
$$d_v(z) = 5$$
, $d_x(z) = 3$, $d_w(z) = 3$

B-F equation says:

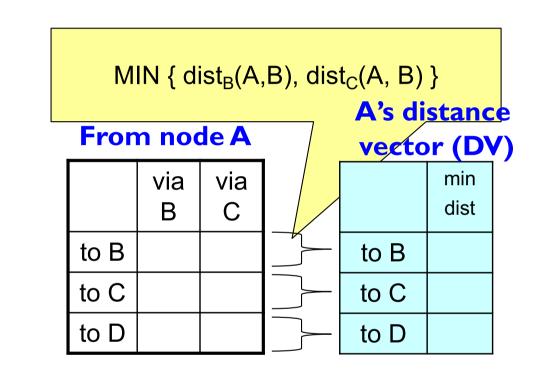

$$d_{u}(z) = \min \{ c(u,v) + d_{v}(z), \\ c(u,x) + d_{x}(z), \\ c(u,w) + d_{w}(z) \}$$

$$= \min \{ 2 + 5, \\ 1 + 3, \\ 5 + 3 \} = 4$$

node achieving minimum is next hop in shortest path, used in forwarding table

Each router maintains its shortest distance to every destination via each of its neighbours

Each router computes its shortest distance to every destination via <u>any</u> of its neighbors

From node A

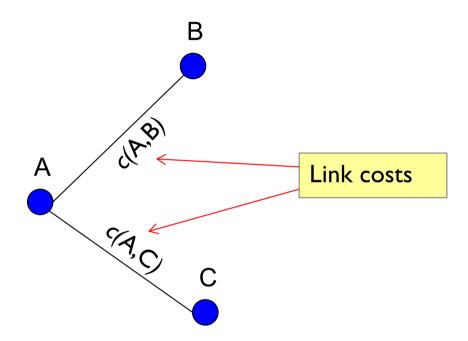

A

	via B	via C
to B	?	?
to C	?	?
to D	?	?

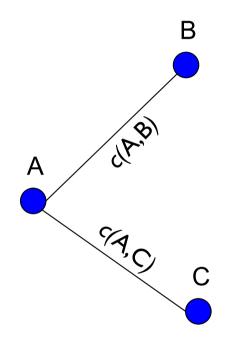

A's DV

	min dist
to B	?
to C	?
to D	?

How does A initialize its dist() table and DV?

How does A initialize its dist() table and DV?

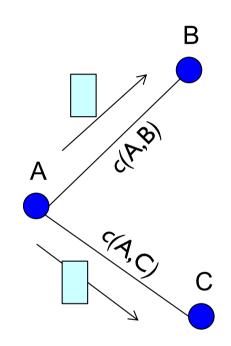

From node A

	via B	via C
to B	c(A,B)	∞
to C	8	c(A,C)
to D	8	∞

A's DV

	mindist
to B	c(A,B)
to C	c(A,C)
to D	∞

Each router initializes its dist() table based on its immediate neighbors and link costs

Assume that A's DV is as follows at some later time

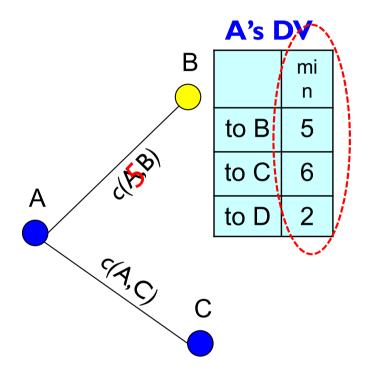

From node A

	via B	via C
to B	c(A,B)	∞
to C	∞	c(A,C)
to D	∞	∞

A's DV

	mindist
to B	5
to C	6
to D	2

Each router sends its DV to its immediate neighbors

From node B				
	/ via	via C		
	Α			
to A	5	8		
to C	15	1		
to D	00	8		

mindist

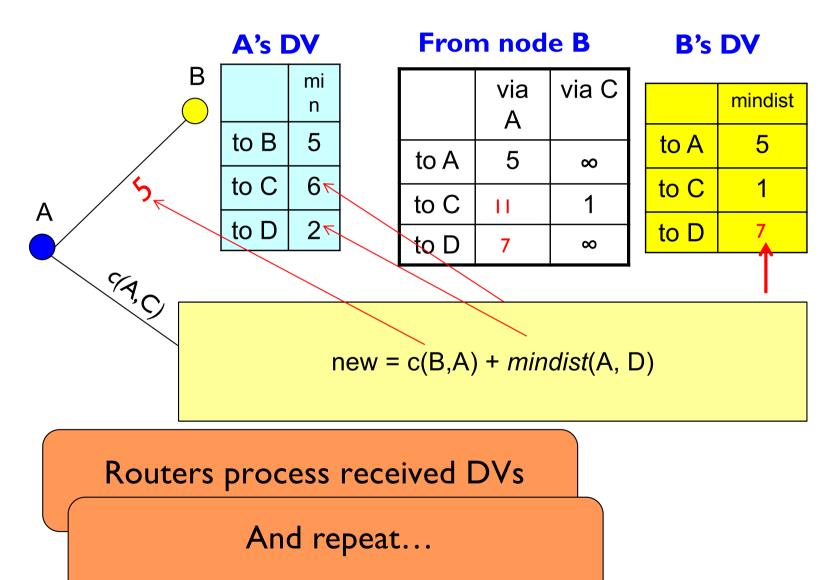

to A 5

to C 1

to D ∞

B's DV

Routers process received DVs

Distance Vector Routing

- Each router knows the links to its neighbors
- Each router has provisional "shortest path" to every other router -- its distance vector (DV)
- Routers exchange this DV with their neighbors
- Routers look over the set of options offered by their neighbors and select the best one
- Iterative process converges to set of shortest paths

Distance vector routing

iterative, asynchronous: each local iteration caused by:

- local link cost change
- DV update message from neighbor

distributed:

- each node notifies neighbors only when its DV changes
 - neighbors then notify their neighbors if necessary

each node:

wait for (change in local link cost or msg from neighbor) recompute estimates if DV to any dest has changed, *notify* neighbors

Distance Vector

if (there is a change in mindist(A, *))

16

17 forever

send mindist(A, *) to all neighbors

- c(i,j): link cost from node i to j
- dist_Z(A,V): shortest dist. from A to V via Z
- mindist(A,V): shortest dist. from A to V

0 At node A 1 Initialization: for all destinations V do if V is neighbor of A $dist_V(A, V) = mindist(A,V) = c(A,V);$ 5 else $dist_{V}(A, V) = mindist(A, V) = \infty$; **send** mindist(A, *) to all neighbors loop: wait (until A sees a link cost change to neighbor V /* case 1 */ or until A receives mindist(V,*) from neighbor V) /* case 2 */ if (c(A, V) changes by $\pm d)$ /* \leftarrow case 1 */ 11 for all destinations Y do 12 $dist_{\vee}(A, Y) = dist_{\vee}(A, Y) \pm d$ else $/* \leftarrow$ case 2: */ 14 for all destinations Y do 15 $dist_V(A, Y) = c(A, V) + mindist(V, Y);$ update mindist(A, *) 16

Distance Vector

Intuition

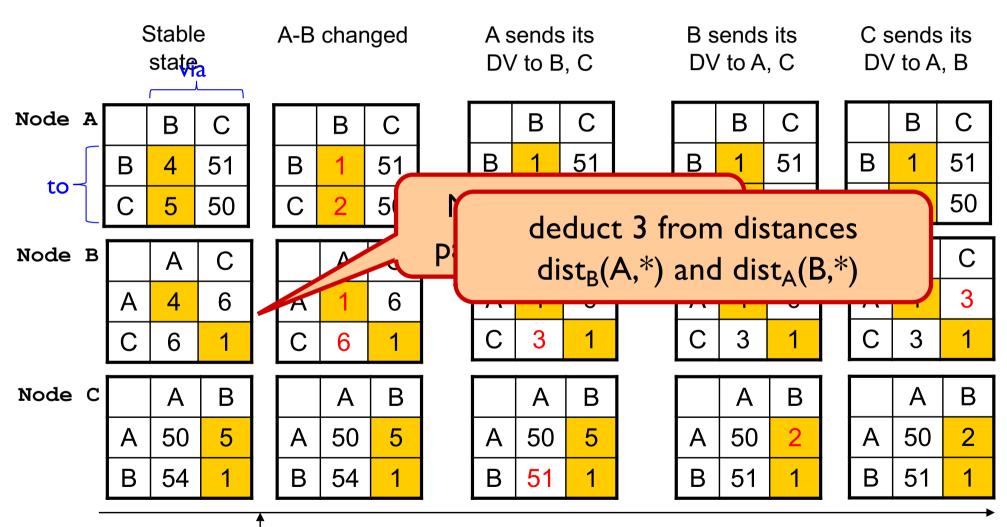

- Initial state: best one-hop paths
- One simultaneous round: best two-hop paths
- Two simultaneous rounds: best three-hop paths
- ***** ...
- Kth simultaneous round: best (k+1) hop paths
- Must eventually converge
 - as soon as it reaches longest best path
-but how does it respond to changes in cost?

Problems with Distance Vector

- A number of problems can occur in a network using distance vector algorithm
- Most of these problems are caused by slow convergence or routers converging on incorrect information
- Convergence is the time during which all routers come to an agreement about the best paths through the internetwork
 - whenever topology changes there is a period of instability in the network as the routers converge
- Reacts rapidly to good news, but leisurely to bad news

DV: Link Cost Changes

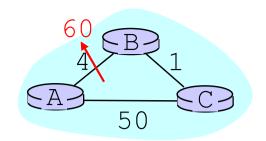

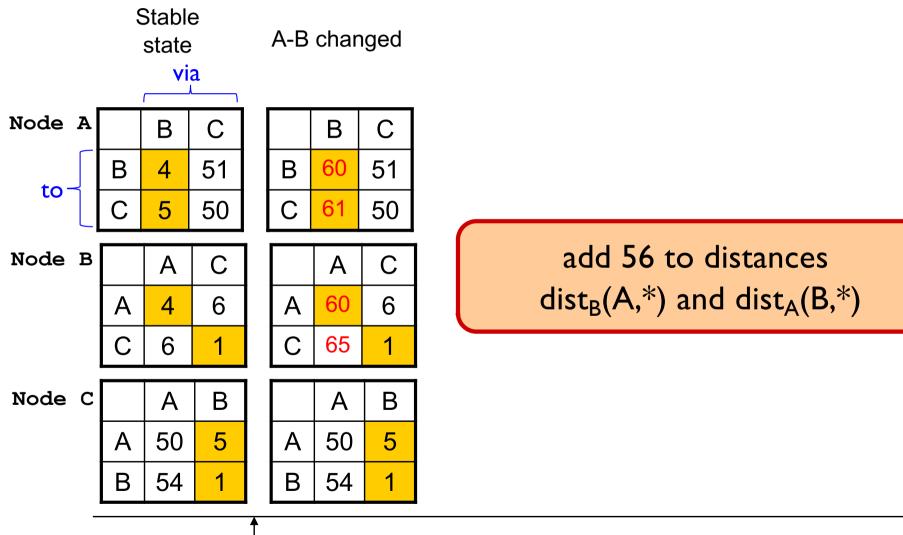

Link cost changes here

"good news travels fast"

DV: Link Cost Changes

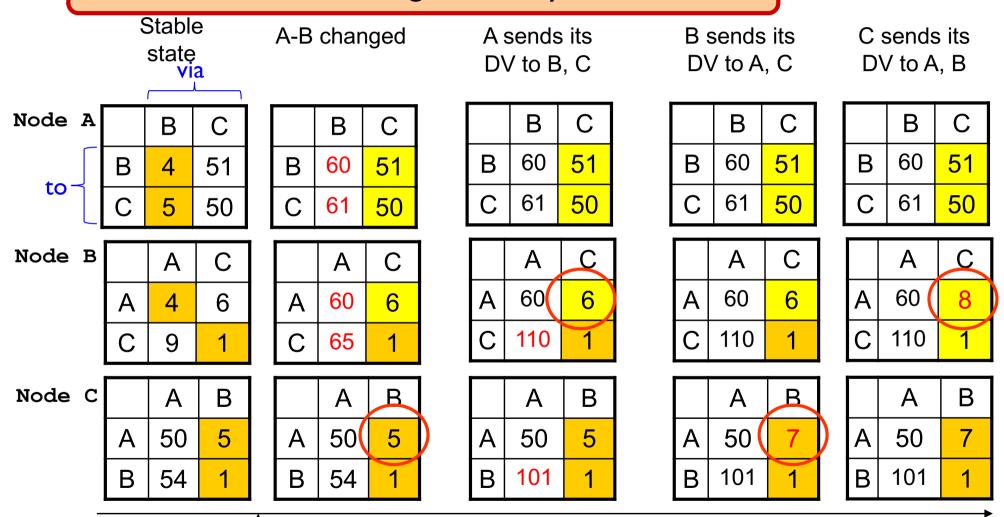

Link cost changes here

DV: Link Cost Changes

60 B 50

This is the "Counting to Infinity" Problem

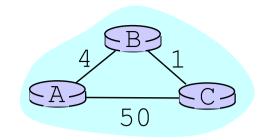

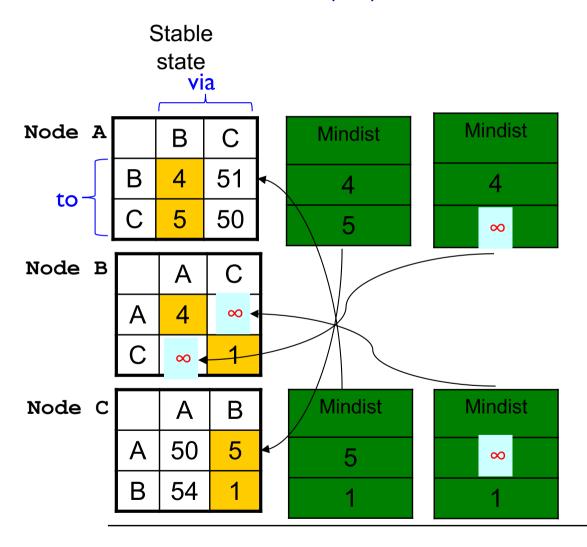

Link cost changes here

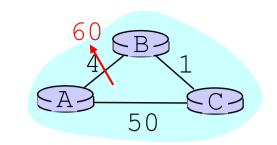

"bad news travels slowly" (not yet converged)

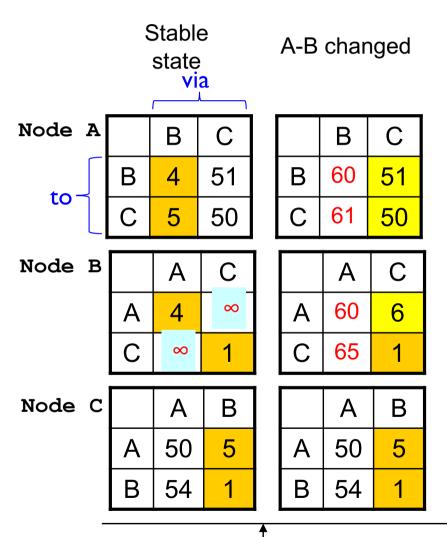

The "Poisoned Reverse" Rule

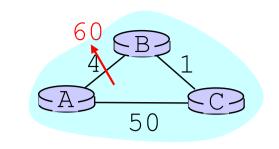

- Heuristic to avoid count-to-infinity
- If B routes via C to get to A:
 - B tells C its (B's) distance to A is infinite (so C won't route to A via B)

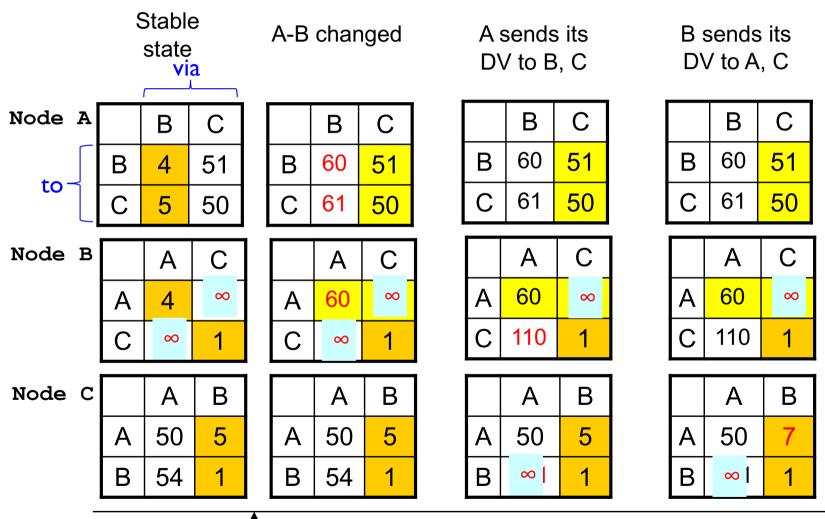

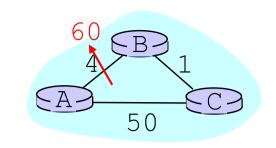

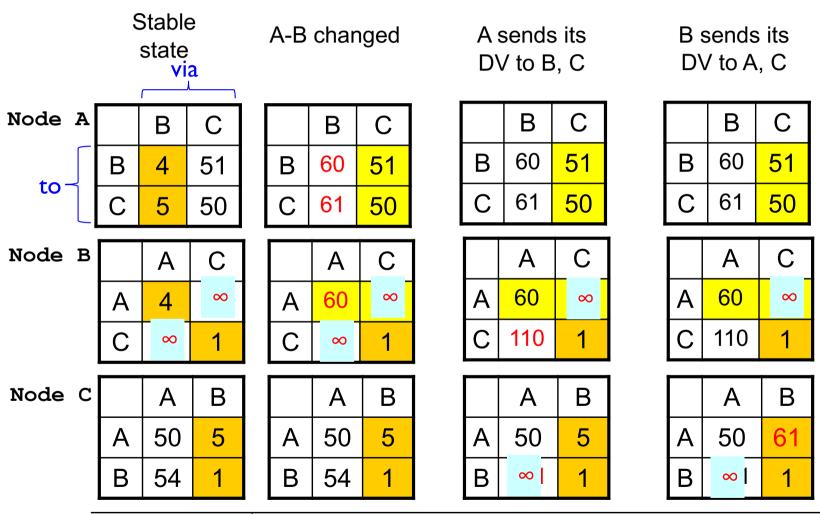

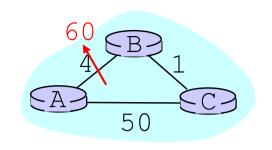

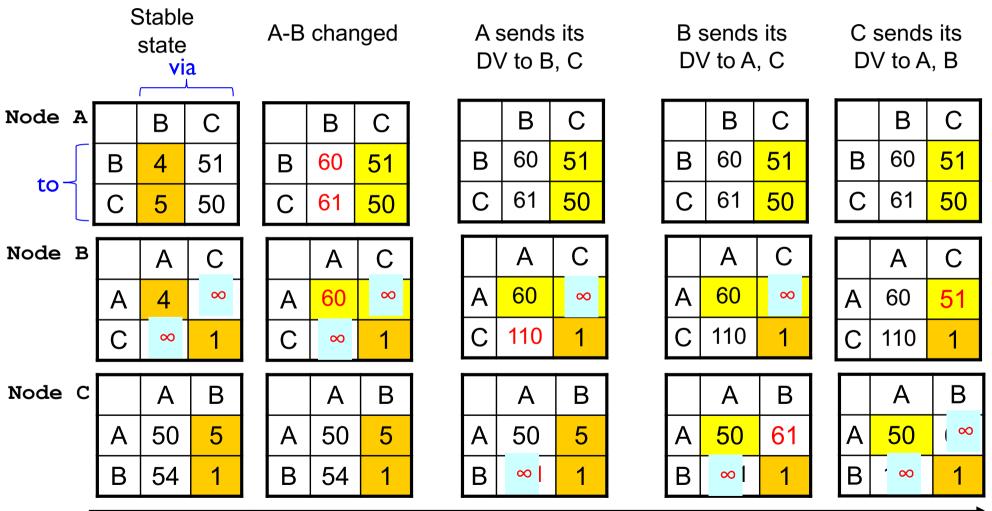

If B routes through C to get to A:

B tells C its (B's) distance to A is infinite

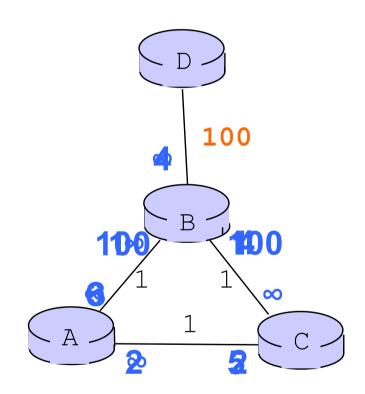

Link cost changes here

Converges after C receives another update from B 8

Will Poison-Reverse Completely Solve the Count-to-Infinity Problem?

Numbers in blue denote the best cost to destination D advertised along the link

Quiz: Link-state routing

- In link state routing, each node sends information of its direct links (i.e., link state) to ?
- A. Immediate neighbours
- B. All nodes in the network
- C. Any one neighbor
- D. No one

www.zeetings.com/salil

Quiz: Distance-vector routing

- In distance vector routing, each node shares its distance table with
- A. Immediate neighbours
- B. All nodes in the network
- C. Any one neighbor
- D. No one

www.zeetings.com/salil

Quiz: Distance-vector routing

- Which of the following is true of distance vector routing?
- A. Convergence delay depends on the topology (nodes and links) and link weights
- B. Convergence delay depends on the number of nodes and links
- C. Each node knows the entire topology
- D. A and C
- E. B and C

www.zeetings.com/salil

Comparison of LS and DV algorithms

message complexity

- LS: with n nodes, E links, O(nE) msgs sent
- DV: exchange between neighbors only
 - convergence time varies

speed of convergence

- LS: O(n²) algorithm requires
 O(nE) msgs
 - may have oscillations
- DV: convergence time varies
 - may be routing loops
 - count-to-infinity problem

robustness: what happens if router malfunctions?

LS:

- node can advertise incorrect link cost
- each node computes only its own table

DV:

- DV node can advertise incorrect path cost
- each node's table used by others
 - error propagate thru network

Real Protocols

Link State

Open Shortest Path First (OSPF)

Intermediate system to intermediate system (IS-IS)

Distance Vector

Routing Information Protocol (RIP)

Interior Gateway Routing Protocol (IGRP-Cisco)

Border Gateway Protocol (BGP)

Network layer, control plane: outline

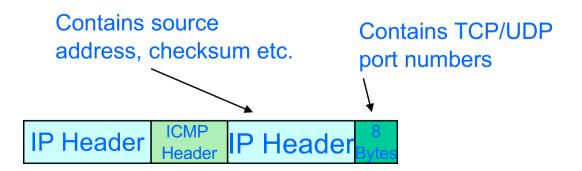

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- hierarchical routing

5.6 ICMP: The Internet Control Message Protocol

Self study (not on exam)

ICMP: Internet Control Message Protocol

- Used by hosts & routers to communicate network level infromation
 - Error reporting: unreachable host, network, port
 - Echo request/reply (used by ping)
- Works above IP layer
 - ICMP messages carried in IP datagrams
- ICMP message: type, code plus IP header and first
 8 bytes of IP datagram payload causing error

ICMP: Internet Control Message Protocol

Type	Code	Description
0	0	echo reply(ping)
3	0	dest. network unreachable
3	I	dest host unreachable
3	3	dest port unreachable
3	4	frag needed; DF set
8	0	echo request(ping)
11	0	TTL expired
11	I	frag reassembly time exceeded
12	0	bad IP header

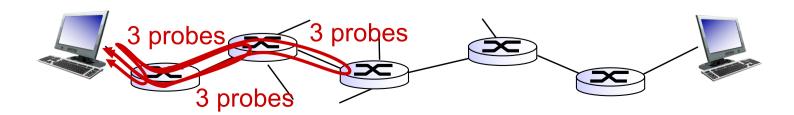

Traceroute and ICMP

- Source sends series of UDP segments to dest
 - first set has TTL = I
 - second set has TTL=2, etc.
 - unlikely port number
- When nth set of datagrams arrives to nth router:
 - router discards datagrams
 - and sends source ICMP messages (type II, code 0)
 - ICMP messages includes IP address of router

when ICMP messages arrives, source records RTTs

stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns ICMP "port unreachable" message (type 3, code 3)
- source stops
